1 Chapter 21 - Electric Charge

1.1 Charge

1. Matter is composed of specific particles (electrons, protons, and neutrons), each with a property of charge (-ve, +ve, or 0)
   (a) Electrons have a charge of $-1.6 * 10^{-19}C$ and a mass of $9.11 * 10^{-31}kg$
   (b) Protons have a charge of $-1.6 * 10^{-19}C$ and a mass of $1.673 * 10^{-27}kg$
   (c) Neutrons have a charge of $0C$ and a mass of $1.674 * 10^{-27}kg$, such that the mass is approximately the sum of that of an electron and proton
2. The Law of Charges state that like charges repel and unlike charges attract
3. Quantization of Charge states that the charge of any body is equal to the multiple of the charge of an electron/proton
4. Materials can be divided into conductors, insulators, and semiconductors
   (a) The distance between the atomic radiuses of each of the atoms in the material determine the type, such that the further the distance, the less conductive, making conductors dense
   (b) Conductors have electrons free to move from orbit to orbit, such as metals
      i. It is noted that this creates the difference of charged conducting bodies, such that the charges isolate themselves on the edges of the object, unlike insulators which are dispersed evenly
   (c) Insulators have a large energy gap (E_g), such that the electrons are bound to atoms, unable to jump/move, such as wood, glass, and rubber
   (d) Semiconductors are not free or bound, such that they can be converted to either a conductor or insulator
      i. Addings impurities to the material through doping allows electrons to jump easier, such that it conducts better
      ii. Increasing temperature increases electron energy, allowing jumps temporarily, while decreasing temperature does the opposite

1.2 Charging

1. Charging by friction is done by rubbing objects together, using the frictional force to force electron transfer to the material with greater attraction to electrons
   (a) Valence electrons are the ones lost from the material
   (b) Glass and silk are known for producing positively charged glass
   (c) Plastic and fur are known for producing negatively charged plastic
2. Charging by contact is done by contact between two non-insulators, causing the charge to move until equilibrium
3. Charging by induction is done by placing a charged rod near a neutral conductor, such that the material is polarized into a seperation of charges, giving a temporary charge
   (a) If the object is then split up in the case of a conductor, where the polarization is on a super-molecular scale, it can be charged
   (b) If the object is an insulator, such that it is on a dipole molecular scale, it is temporary, but can allow it to be attracted to the object
4. Electroscopes have two flat leaves connected to a rod, which is attached to the ball on top, such that it detects charge by charging by contact, after which the leaves seperate
   (a) It can be decharged by attaching it to a grounding wire, attached to the Earth, which acts as a giant neutral body to neutralize the charges

1.3 Coulomb's Law

1. $F_e = \frac{k|q_1||q_2|}{r^2}$, where the direction of the vector is determined by the law of charges
   (a) $k = 9 * 10^9 \frac{Nm^2}{C^2} = \frac{1}{4\pi\epsilon_0}$
   (b) The overall force must be found before breaking it up into components, rather than in finding it as components first
2. The ratio of electrostatic force to gravitational force on a molecular scale approximates as 10^{40}, such that gravity can be ignored on that scale
   (a) Based on the hydrogen atom, with a radius of 0.53 Angstrom ($0.53 * 10^{-10}m$)

2 Chapter 22 - Electric Field

2.1 Point Charges

1. The electric field ($\vec{E}$) is related to the number of field lines per unit area, such that lines are drawn from positive to negative
   (a) Electric fields are found by measuring the force on a positive test charge with a small enough size that it doesn't disrupt the surrounding field
   (b) $\vec{E} = \frac{\vec{F}}{q_0} = \frac{k|q|}{r^2}$, where the direction is determined by the type of charge, where q_0 is the test charge, and q is the charge of the point mass producing the field
2. Dipole moments are created by two point charges of opposite charge, seperated by some distance
   (a) Dipole moment $(P) = qr$, where r is the distance between them, and q is the charge of each point, for cases where the charges are of equal, but opposite charge, moving from negative to positive
   (b) Thus, $\tau = PxE$ and $PE = -E \cdot P$ for dipole moments

2.2 Solid Bodies

1. $\vec{E} = \sum_i \frac{k\Delta q_i}{r_i^2} = \int \frac{k}{r^2} dq$
   (a) $q = \lambda x, q = \sigma A, q = \rho V$ (depending on the dimensions of the solid body)
   (b) If the density functions are non-uniform, the integral is taken to solve for q, with respect to each dimension variable
2. These calculations can be made simpler if one of the dimensions of the field cancels out, but a multiplier of some trig function must be added to the equation to remove that component
3. For parallel plates, $\vec{E} = \frac{\sigma}{\epsilon_0}$, such that each plate is half of that value, where ϵ_0 is the permittivity of free space, or $8.854 * 10^{-12}C^2/Nm^2$, and σ is the charge density of the plates

3 Chapter 23 - Electric Flux

3.1 Electric Flux

1. Electric flux is the number of electric field lines passing through an area, such that $\Phi_E = \vec{E} \cdot \vec{A}_n = \vec{E}\vec{A}_n cos(\theta)$, where $\vec{A}_n$ is the normal to the surface, perpendicular and with a magnitude equal to the area

(a) For an enclosed object, lines entering the surface of the object is negative, outward is positive

(b) Thus, positive objects have lines entering but not leaving, negative objects have vice versa

2. $\Phi = \vec{E} \cdot \vec{A}_n$ for uniform surfaces

    (a) $\Phi = \lim_{\Delta A_n \to 0} \sum_i \vec{E}_i \cdot \Delta A_n = \oint \vec{E} \cdot dA_n$

3.2 Gauss's Law

1. Gauss's Law is used to calculate the graviational field at a point, by creating a gaussian surface including that point

    (a) Gaussian surfaces must be closed (compact/effectively-continuous without boundary in any direction), 3D surfaces, such that they are the boundary of a 3D region with a constant field throughout (symmetrical)

    (b) The electric field must also be parallel to the normal of the tangent plane, A_N, on the surface A

    (c) $\Phi_e = \oint \vec{E} dA = \vec{E} \oint dA = \frac{kq_{enc}}{r^2}(4\pi r^2) = \frac{q_{enc}}{\epsilon_0}$, where q_{enc} is the charge of the body inside the surface creating the field, and the surface integral of dA is the surface area
